

## The Potassium Fluoride-Boric Acid System. Hydrogen Bonding in $\text{KF} \cdot \text{H}_3\text{BO}_3$

By John Emsley,\* Victor Gold, and Jeremy Lucas, Department of Chemistry, King's College, Strand, London WC2R 2LS  
Richard E. Overill, Computer Unit, King's College, Strand, London WC2R 2LS

*Ab initio* LCAO-MO-SCF calculations have been performed on the most likely interactions between  $\text{F}^-$  and  $\text{H}_3\text{BO}_3$ . These show that the monofluoroborate ion  $[\text{BF}(\text{OH})_3]^-$  is the most stable, but only by 33 kJ mol $^{-1}$  relative to the hydrogen-bonded system  $\text{F}^- \cdots \text{HOB}(\text{OH})_2$ . Infrared analysis of the solid phase of composition  $\text{KF} \cdot \text{H}_3\text{BO}_3$ , which grows from an aqueous solution of KF and  $\text{H}_3\text{BO}_3$ , shows the hydrogen-bonded structure to be the preferred form. The results of  $^{19}\text{F}$  and  $^{11}\text{B}$  n.m.r. studies on aqueous solutions of KF and  $\text{H}_3\text{BO}_3$  are also consistent with hydrogen bonding being the chief interaction although it is possible that an equilibrium exists involving  $[\text{BF}(\text{OH})_3]^-$  since  $[\text{BF}_3(\text{OH})]^-$  is detectable in such solutions.

THE tetrafluoroborate ion  $\text{BF}_4^-$  and its hydroxy-derivatives  $[\text{BF}_n(\text{OH})_{4-n}]^-$  have a history of investigation going back to the time of Berzelius.<sup>1</sup> In more recent times a clearer understanding of the species and equilibria involved in solutions of  $\text{BF}_4^-$  has been realised<sup>2</sup> and one review discusses all the possible ions *i.e.*  $n = 1, 2$ , or  $3$ .<sup>3</sup> We are of the opinion that evidence for  $[\text{BF}(\text{OH})_3]^-$  is still lacking.

The ion  $[\text{BF}(\text{OH})_3]^-$  was first postulated as an intermediate in the hydrolysis of  $\text{HBF}_4$  in dilute solutions.<sup>4</sup> The potassium salt,  $\text{K}[\text{BF}(\text{OH})_3]$ , was reported to form from an aqueous solution of KF and  $\text{H}_3\text{BO}_3$ <sup>5a</sup> and the structure was deduced from conductimetric and thermometric calculations supported by an i.r. spectrum which displayed a band at 790 cm $^{-1}$  said to be characteristic of  $\nu(\text{B}-\text{F})$ .<sup>5b</sup>

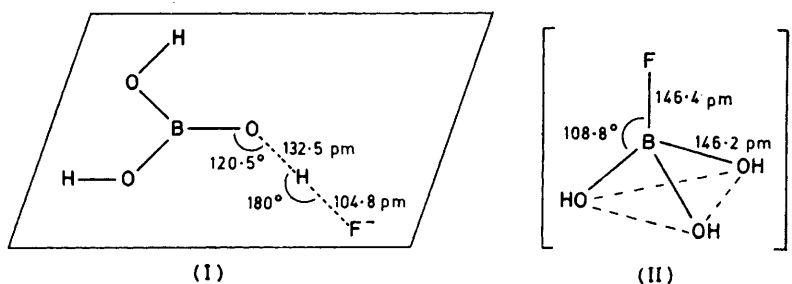

Fluorine-19 n.m.r. investigations of  $\text{BF}_4^-$  and its hydrolysis products showed clear signals attributable to  $[\text{BF}_3(\text{OH})]^-$  and  $[\text{BF}_2(\text{OH})_2]^-$  with  $J_{\text{BF}}$  ca. 14–15 Hz, but the signal for the supposed  $[\text{BF}(\text{OH})_3]^-$  was absent.

Recently *ab initio* calculations have been made on several simple boron compounds including  $\text{H}_3\text{BO}_3$  as a hydrogen-bonded dimer,<sup>8</sup> as well as on the ions  $[\text{BF}_4]^-$  (ref. 9) and  $[\text{BF}_3(\text{OH})]^-$ .<sup>10</sup> This technique has been used by us to some advantage in probing the very strong hydrogen bonding between  $\text{RCO}_2\text{H}$  and  $\text{F}^-$ .<sup>11</sup> Considering the well known propensity for hydrogen bonding of  $\text{H}_3\text{BO}_3$ <sup>12</sup> it seemed likely that it too would form a strong hydrogen bond to  $\text{F}^-$ .

### THEORETICAL

*Ab initio* LCAO-MO-SCF calculations have been performed on boric acid, boric acid-fluoride, the fluorotrihydroxyborate ion, and the borate ion,  $\text{H}_2\text{BO}_3^-$ , using a version of the program GAUSSIAN 76.<sup>13</sup> This program has recently been modified to perform level-shifting of the Hartree-Fock Hamiltonian<sup>14</sup> directly in the atomic orbital basis to guarantee the convergence of the iterative SCF calculations.<sup>15</sup>

Geometry optimizations (bond lengths to within  $\pm 1$  pm, bond angles to within  $\pm 0.1^\circ$ ) were performed with the

Instead a broad band was observed and it was suggested that this represented a time average signal for this ion and for free fluoride in solution, there being rapid exchange of fluorine between these two environments.<sup>6</sup> No explanation for the special mobility of the B-F bond in this ion was advanced, but other evidence, again based on  $^{19}\text{F}$  n.m.r. spectroscopy,<sup>7</sup> shows that several equilibria may be involved in these systems and it has been suggested that the ion  $[\text{BF}_2(\text{OH})_2]^-$  may disproportionate to  $[\text{BF}_3(\text{OH})]^-$  and  $\text{F}^-$  without the need for postulating  $[\text{BF}(\text{OH})_3]^-$ .

split-valence 4-31G basis set,<sup>16</sup> using standard univariate quadratic interpolation procedures.

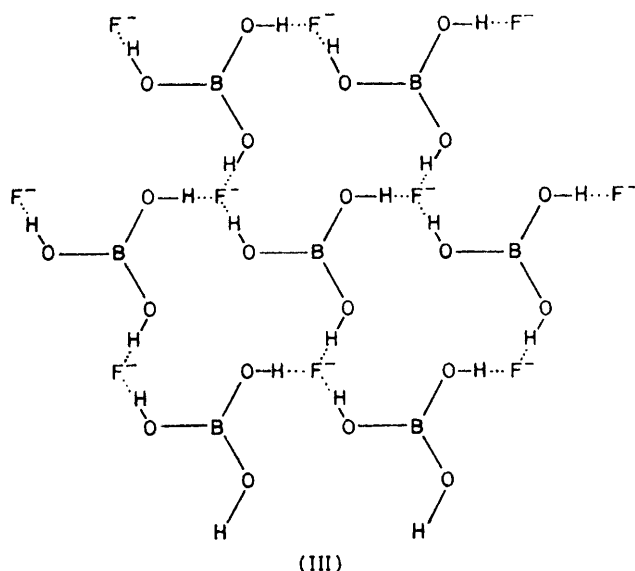

(a) *Boric acid*,  $\text{B}(\text{OH})_3$ . Starting from the experimental geometry<sup>17</sup> of  $r(\text{BO}) = 136.2$  pm,  $r(\text{OH}) = 94.6$  pm,  $\text{BOH} = 114.3^\circ$ ,  $\text{OBO} = 120^\circ$ , the optimization yielded  $r(\text{OH}) = 95.0$  pm and  $\text{BOH} = 120.5^\circ$ ,  $\text{OBO} = 120^\circ$  and the dihedral angle  $\text{OBOH} = 0^\circ$ , giving  $C_{3h}$  symmetry for  $\text{H}_3\text{BO}_3$ .

(b) *Boric acid-fluoride*,  $[\text{B}(\text{OH})_2(\text{O}'\text{H}'\text{F})]^-$ . Starting from the optimized geometry for boric acid above, the optimization yielded  $r(\text{BO}') = 135.8$  pm,  $r(\text{O}'\text{H}') = 132.5$  pm,  $r(\text{H}'\text{F}) = 104.8$  pm, and  $\text{BO}'\text{H}' = 133.5^\circ$  under the assumption that the hydrogen bond is linear as in (I).

(c) *Fluorotrihydroxyborate ion*,  $[\text{BF}(\text{OH})_3]^-$ . Starting from a pyramidal geometry based on the structure for boric acid above, the optimization yielded  $r(\text{BF}) = 146.4$  pm,  $r(\text{BO}) = 146.2$  pm,  $\text{FBO} = 108.8^\circ$ , and the dihedral angle  $\text{FBOH} = 90^\circ$ , maintaining  $C_3$  symmetry, structure (II).

(d) *Borate ion*,  $\text{B}(\text{OH})_3\text{O}^-$ . Starting from the optimized geometry for boric acid above, the optimization yielded  $r(\text{BO}) = 143.6$  pm,  $r(\text{BO}') = 129.5$  pm, and  $\text{OBO} = 120^\circ$ .

The hydrogen-bond energy of (I) and the stability of (II) were then computed using the extended  $[4s2p/2s1p]$  basis set of Dunning<sup>18</sup> with an  $s$ -orbital scaling factor of  $\sqrt{2}$  and a  $p$ -orbital exponent of 0.7 for the protons. This basis set has been shown to be sufficiently complete to yield hydrogen-bond energies which are stable against further basis set extensions<sup>11</sup> and against 'ghost orbital' cor-

rections.<sup>19</sup> Single determinant SCF wavefunctions are generally adequate for calculations of the energies of strong hydrogen bonds between closed-shell molecules since the molecular extra correlation energy and the zero-point vibrational corrections are both small (*ca.* 5%).<sup>20</sup> The results of the calculations are presented in Table I.

#### EXPERIMENTAL

**Instruments.**—Fluorine-19 n.m.r. spectra were run on a Bruker HFX90 machine operating at 84.66 MHz and the samples were referenced to  $\text{CFCl}_3$ ;  $^{11}\text{B}$  n.m.r. spectra were run on a Bruker WM250 machine operating at 80.239 MHz and the samples were referenced to  $\text{BF}_3\cdot\text{Et}_2\text{O}$ . Infrared spectra were recorded on a Perkin-Elmer 457 spectrometer the samples being studied as KBr discs.

**Solubility.**—The solubility of KF in water at 20 °C (94.0 g per 100 cm<sup>3</sup>) and  $\text{H}_3\text{BO}_3$  (4.96 g per 100 cm<sup>3</sup>) is significantly increased by the addition of the other. With an equimolar ratio the solubility of  $\text{H}_3\text{BO}_3$  can reach 128 g per 100 cm<sup>3</sup> but the effect is only temporary. The solution grows viscous and after *ca.* 10 min an amorphous white solid of composition  $\text{KF}\cdot\text{H}_3\text{BO}_3$  precipitates from solution. This is a homogeneous material, m.p. 84 °C (lit.,<sup>5</sup> 88 °C) (Found: H, 2.50; B, 9.20; K, 32.5. Calc. for  $\text{KF}\cdot\text{H}_3\text{BO}_3$ : H, 2.50; B, 9.00; K, 32.6%). The solubility of this in water at 20 °C is 39.55 g per 100 cm<sup>3</sup> (saturated solution = 3.30

mol dm<sup>-3</sup>), and the solution is very viscous. The i.r. spectrum of  $\text{KF}\cdot\text{H}_3\text{BO}_3$  is listed in Table 2. The compound  $\text{KF}\cdot\text{H}_3\text{BO}_3$  can also be prepared from KF and  $\text{H}_3\text{BO}_3$  in methanol. Again the solubility of the least soluble component, this time KF, is significantly raised but only

#### DISCUSSION

The addition of KF to boric acid in aqueous solution increases its solubility but only temporarily. Within minutes the solution becomes very viscous, reminiscent of fluoride solutions in acetic acid,<sup>21</sup> and a white solid settles out of composition  $\text{KF}\cdot\text{H}_3\text{BO}_3$ . That a similar substance is not produced from NaF solutions suggests that there is no common ion  $[\text{BF}(\text{OH})_3]^-$  in these

solutions in any appreciable concentration, only  $F^-$ . Indeed the object of this paper is to show that  $KF \cdot H_3BO_3$  is a hydrogen-bonded material of boric acid and fluoride, yet the theoretical results indicate that  $[BF(OH)_3]^-$  is slightly more stable.

It has recently been argued that the energies of very strong, asymmetric hydrogen bonds between closed-shell molecules should be defined with respect to the pair of component molecules which is closer, either energetically,<sup>22</sup> or structurally,<sup>23</sup> to the hydrogen-bonded system. Using either criterion it is clear that the boric acid-fluoride hydrogen bond should in fact be defined with respect to the borate anion,  $H_2BO_3^-$ , and HF, not  $H_3BO_3$  and  $F^-$ . Based on this definition we compute the hydrogen-bond energy of the  $F^- \cdots H_3BO_3$  system to be  $149 \text{ kJ mol}^{-1}$ ,\* placing it on a par with other strong hydrogen bonds to fluoride such as  $F^- \cdots H_2NCOR$  ( $\Delta E = 149 \text{ kJ mol}^{-1}$ ),<sup>24</sup>  $F^- \cdots HO_2CR$  ( $\Delta E = 105 \text{ kJ mol}^{-1}$ ),<sup>11</sup> and  $F^- \cdots H_2O$  ( $\Delta E = 101 \text{ kJ mol}^{-1}$ ).<sup>25</sup>

The recently described  $F^- \cdots HONO_2$  hydrogen bond may also fall into this category.<sup>26</sup>

There have been only two previous *ab initio* calculations involving boric acid.<sup>8,27</sup> In one of these,<sup>8</sup> a value of  $59 \text{ kJ mol}^{-1}$  was calculated for the stabilization energy of the boric acid dimer, but unfortunately a minimal STO-3G basis set was used and no geometry optimization was performed so this result must be regarded critically. Our calculations predict that the isolated fluorotrihydroxyborate anion (II) to be more stable than the isolated boric acid-fluoride complex (I) by  $33 \text{ kJ mol}^{-1}$ .

The fluoride affinity of  $BF_3$  has recently been calculated to be  $539 \text{ kJ mol}^{-1}$  using the 4-31G basis set,<sup>28</sup> and this may be compared with our 4-31G value for boric acid of  $294 \text{ kJ mol}^{-1}$ . However, our result with the larger basis set, of  $204 \text{ kJ mol}^{-1}$ , is almost certainly more reliable.

The compound which has the correct composition for  $K[BF(OH)_3]$  does not have the expected i.r. spectrum and we did not observe a strong band at  $790 \text{ cm}^{-1}$  as did the original discoverers of the solid.<sup>5</sup> The i.r. spectrum of our material (Table 2) shows no absorptions in the region  $710\text{--}870 \text{ cm}^{-1}$ , which is where  $K[BF_4]$  has a line at  $777 \text{ cm}^{-1}$  and  $K[BF_3(OH)]$  at  $790 \text{ cm}^{-1}$  that can be attributed to  $\nu(BF)$ . Nor do we find bands that we can identify as arising from a tetrahedral boron framework such as  $[B(OH)_4]^-$  displays at  $945$  and  $754 \text{ cm}^{-1}$ ,<sup>29</sup> and  $[BF_3(OH)]^-$  displays at  $1000$  and  $750 \text{ cm}^{-1}$ . These are regions of the spectrum in which  $KF \cdot H_3BO_3$  shows nothing.

What is most striking about  $KF \cdot H_3BO_3$  is its i.r. resemblance to  $H_3BO_3$ . Thus the modes associated with the vibrations of the planar  $BO_3$  unit are present at  $1380\text{--}1450 [\nu_{as.}(BO_3)]$ , ca.  $880 [\nu_s(BO_3)]$ ,  $670 [\pi(BO_3)$ , out-of-plane bend], and ca.  $550 \text{ cm}^{-1} [\delta(BO_3)$ , in-plane bend] in both compounds.<sup>30</sup> Three of these can be identified by their doublet structure due to  $^{10}B$  and  $^{11}B$  isotopes and the isotope ratio of frequencies  $1.029 : 1$ .

\* Calculated with respect to  $F^- + H_3BO_3$  the energy is  $170.5 \text{ kJ mol}^{-1}$ .

The identification of the hydrogen modes was similarly aided by the recrystallization of the solid from  $D_2O$  which gave a partially deuteriated material whose spectrum in Table 2 shows bands at:  $2380$ ,  $2200 [\nu(OD)]$ ;  $830 [8(OD)]$ ; and  $630 \text{ cm}^{-1} [\gamma(OD)]$  thus identifying the regions of the three hydrogen-bonded OH modes as:  $3300$ ;  $3030$ ;  $1240$ ;  $1130$ ; and  $880 \text{ cm}^{-1}$ . The  $1240 \text{ cm}^{-1}$  band on deuteration would fall at  $918 \text{ cm}^{-1}$  which coincides with  $\nu_s(BO_3)$ .

The i.r. spectrum shows  $KF \cdot H_3BO_3$  not to have structure (II). Nor does it have discrete very strong hydrogen bonds of type (I) since such a system would give rise to the characteristic continuum below  $1600 \text{ cm}^{-1}$  caused by very strong hydrogen bonding.<sup>31</sup> Moreover, the stretching and in-plane bending modes of the hydrogen bonds appear as double peaks, which might be explained by their being both  $OH \cdots F$  and  $OH \cdots O$  hydrogen bonds in the system. It is possible to draw a planar hydrogen-bonded structure for  $KF \cdot H_3BO_3$  which preserves the planarity of the bonding around the boric acids, as in  $H_3BO_3$  itself, and this is shown in (III). In effect each fluoride ion serves to form three hydrogen bonds thus linking the  $F^- \cdots H_3BO_3$  units of (I) into a planar array of hydrogen bonding. Within the three hydrogen bonds at each fluoride it might conceivably be that there is approximate proton transfer as in (I) so that the  $C_3$  symmetry at fluoride is reduced to  $C_2$ . The result would be that instead of the expected four hydrogen modes of  $C_3$  symmetry we should observe six modes for  $C_2$ . Five of these are observed (Table 2) and labelled  $\nu_s$ ,  $\nu_s'$ ,  $\delta$ ,  $\delta'$ , and  $\gamma$ .

If, as is postulated for  $KF \cdot H_3BO_3$ , the hydrogen-bonding arrangement is like (III) then we would not expect very strong hydrogen-bonding character to display itself and this would explain the absence of an i.r. continuum yet at the same time it would explain why the spectrum resembles that of boric acid itself.

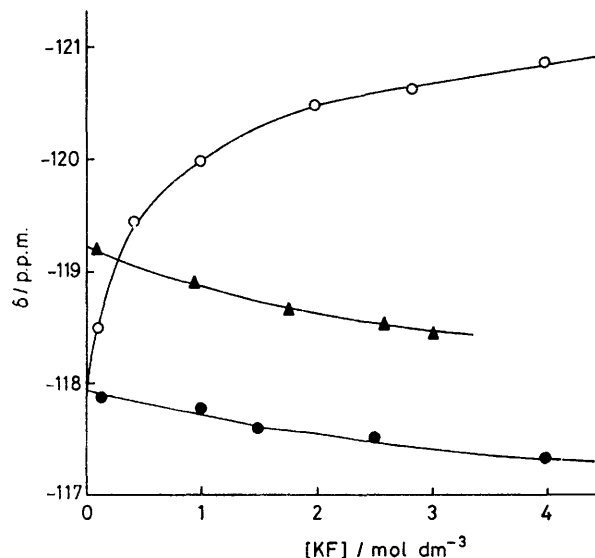

The Figure shows how the chemical shift of the fluoride ion in water varies with concentration, and the effect on this of an equimolar concentration of  $H_3BO_3$ . The most striking effect on the signal is its broadening even in dilute solutions: line width, half-height =  $42 \text{ Hz}$  at  $0.2 \text{ mol dm}^{-3}$ ,  $100 \text{ Hz}$  at  $0.5 \text{ mol dm}^{-3}$ , and  $166 \text{ Hz}$  at  $2.8 \text{ mol dm}^{-3}$ . At low concentrations the broadening is due to hydrogen bonding and becomes progressively greater through viscosity broadening as the concentration increases.

The upfield shift with concentration is also explained by the increased number of fluorides forming two and even three hydrogen bonds to boric acid in solution. That hydrogen bonding causes an upfield shift of  $F^-$  is shown by ( $^{19}F$ ,  $HF_2^-$ ) which is at  $-149.3 \text{ p.p.m.}$ <sup>32</sup> However, the observed upfield shift could also be explained by rapid exchange of  $F^-$  with  $[BF(OH)_3]^-$  since the chemical shift of this can be extrapolated as ca.  $-125 \text{ p.p.m.}$  from the chemical shifts of  $[BF_4]^-$ ,  $-149.5$ ,  $[BF_3(OH)]^-$ ,  $-140.5$ , and  $[BF_2(OH)_2]^-$   $-132.5 \text{ p.p.m.}$  However, it is obvious that even if equilibrium (1) is operative it lies to the left-hand side.

The  $^{19}\text{F}$  spectra of equimolar concentrations of KF and  $\text{H}_3\text{BO}_3$  show a second fluorine signal at  $-141.6$  p.p.m.

which we can equate to  $[\text{BF}_3(\text{OH})]^-$ . This signal shows a quartet structure due to  $J_{\text{BF}}$  of 14.65 Hz. It accounts for ca. 5% of the fluorine nuclei at concentrations of

Fluorine chemical shift (p.p.m.,  $\text{CFCl}_3$ ) of KF in solution at different molarities:  $\text{KF} \cdot \text{H}_3\text{BO}_3$  in water (○);  $\text{KF} \cdot \text{H}_3\text{BO}_3$  in 50 : 50 water-SMe<sub>2</sub>O (▲); KF in water (●)

$2.8 \text{ mol dm}^{-3}$ . The presence of this species, and not  $[\text{BF}_2(\text{OH})_2]^-$ , is consistent with the claim by Maya<sup>7</sup> that the latter exists in equilibrium with  $[\text{BF}_3(\text{OH})]^-$  as in

(2) and that this equilibrium lies to the right-hand side. It is possible to imagine a system involving  $[\text{BF}(\text{OH})_3]^-$

$\text{H}_3\text{BO}_3$  acting on  $\text{F}^-$  is due to hydrogen bonding and not to the formation of  $[\text{BF}(\text{OH})_3]^-$ .

The  $^{11}\text{B}$  n.m.r. spectrum of  $\text{H}_3\text{BO}_3$  shows a broad signal at 19.3 p.p.m. at  $0.1 \text{ mol dm}^{-3}$  concentration. At higher concentrations extremely broad resonances appear in the spectrum that arise from polyborate species affected by quadrupole broadening. The presence of equimolar concentrations of KF causes several changes: the boric acid signal broadens considerably and moves upfield to 15.9 p.p.m. at  $0.8 \text{ mol dm}^{-3}$ ; the underlying broad resonances are more intense; and two new signals appear, a broad one at 13.3 p.p.m. and a sharp one at  $-0.02$  p.p.m. The latter displays  $J_{\text{BF}}$  of ca. 15 Hz and is identified as due to  $[\text{BF}_3(\text{OH})]^-$ .<sup>33</sup>

The signal at 13.3 p.p.m. has no counterpart in the  $^{19}\text{F}$  spectrum and so does not arise from a B-F species. It is probably a polyborate;  $\text{H}_3\text{BO}_3$  solutions to which a small amount of KF is added precipitate a polyborate on standing. This material is under investigation.

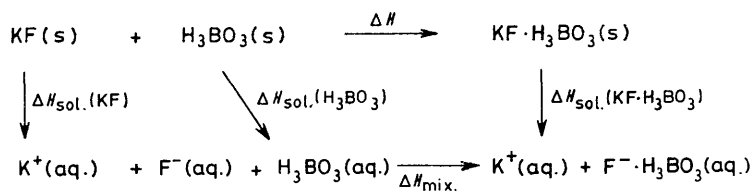

The  $^{11}\text{B}$  spectra show a degree of complexity in these solutions not revealed by  $^{19}\text{F}$  n.m.r. spectroscopy. Nevertheless they do show that the primary species is boric acid and that this is shifted upfield by the presence of  $\text{F}^-$  in solution just as  $\delta(^{19}\text{F})$  is shifted upfield by the presence of  $\text{H}_3\text{BO}_3$ . Both signals exhibit considerable broadening\* which is anticipated if there is strong hydrogen bonding between them.

The thermodynamic cycle below has been tentatively explored by the measurement of  $\Delta H_{\text{mix}}$  and  $\Delta H_{\text{sol}}$ .

$$\Delta H + \Delta H_{\text{sol}}(\text{KF} \cdot \text{H}_3\text{BO}_3) = \Delta H_{\text{sol}}(\text{KF}) + \Delta H_{\text{sol}}(\text{H}_3\text{BO}_3) + \Delta H_{\text{mix}} \quad (3)$$

$$\Delta H = -17.7 + 32.5 - 6.5 - 42.0 = -33.7 \text{ kJ mol}^{-1} \quad (4)$$

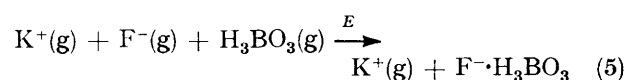

( $\text{KF} \cdot \text{H}_3\text{BO}_3$ ). The related equation (3) gives the value of  $\Delta H$  (4). If the hydrogen-bond energy is defined with

and  $[\text{BF}_2(\text{OH})_2]^-$  but in concentrations too small to be measured by  $^{19}\text{F}$  n.m.r. even if they had sufficiently long lifetimes to be observed as separate species.

With a mixed solvent, 50 : 50  $\text{H}_2\text{O} : \text{SMe}_2\text{O}$ , the  $^{19}\text{F}$  n.m.r. spectrum of an equimolar mixture of KF and  $\text{H}_3\text{BO}_3$  paralleled that of KF in water, but with an upfield solvent shift. This second solvent was chosen as a good hydrogen-bond acceptor, which would compete for  $\text{H}_3\text{BO}_3$ , and at the same time should favour the right-hand side of (1). Clearly this does not happen since the signal moves downfield with increasing concentration as with  $\text{F}^-$  in water. Thus the upfield shift caused by

respect to  $\text{F}^-$  and  $\text{H}_3\text{BO}_3$  by equation (5), and if the lattice energies of KF and  $\text{KF} \cdot \text{H}_3\text{BO}_3$  are assumed to

be equal, we can calculate the minimum value of  $E$  from  $-\Delta H + \Delta H_{\text{sub}}(\text{H}_3\text{BO}_3) = E = 34 + 99 = 133 \text{ kJ}$

\* The  $^{11}\text{B}$  signal of  $0.1 \text{ mol dm}^{-3}$   $\text{KF} \cdot \text{H}_3\text{BO}_3$  is 135 Hz wide at half signal height. The upfield shift of the boron atom of  $\text{H}_3\text{BO}_3$  is expected if it participates in hydrogen bonding, which will cause partial charge transfer to the oxygen which in turn will raise the electron density at boron.

mol<sup>-1</sup>. This value we can compare with the calculated value of 170.5 kJ mol<sup>-1</sup> given as a footnote to p. 785.

In conclusion we have found no evidence for the species [BF(OH)<sub>3</sub>]<sup>-</sup> either in solution or in the solid KF·H<sub>3</sub>BO<sub>3</sub> despite the fact that *ab initio* calculations show this to be slightly more stable than the hydrogen-bonded complex F<sup>-</sup> ··· H<sub>3</sub>BO<sub>3</sub>. The proposed structure (III) might prove to be more stable than (I) and thus be favoured over structure (II). Since we have found evidence for a hydrogen-bonded complex in both the solid state and in solution, it would seem that the extra stability of 33 kJ mol<sup>-1</sup> of the fluorotrihydroxyborate ion over a strongly hydrogen-bonded interaction is insufficient to compensate for other forces such as solvation energies and lattice energies, and equilibrium (1) remains firmly to the left-hand side.
